(E) (a) XRD Diffractogram obtained from the synthesized In<sub>2</sub>S<sub>3</sub>. (b) XRD reference pattern of In<sub>2</sub>S<sub>3</sub> (ref. code 01- 084-1385) 440x173mm (300 x 300 DPI)

Figure 2. A) UV/Vis absorbance spectrum of In<sub>2</sub>S<sub>3</sub>. B) Plot of direct band gap of In<sub>2</sub>S<sub>3</sub>, where  $\alpha$  corresponds to absorption coefficient,  $h$  corresponds to Plank Constant,  $\nu$  to incident photon frequency and  $m$  correspond to the transition ( $m=1/2$  for direct transition). The arrow marks the band gap value of the semiconductor.  
192x135mm (300 x 300 DPI)

Figure 3. Photocatalytic production of H<sub>2</sub> by Dv. [NiFeSe] Hase mixed with In<sub>2</sub>S<sub>3</sub> particles monitored by mass spectrometry. The measurements were performed at 37°C in 50mM Tris-HCl, 0.2 M sodium sulfite at pH 7. The arrows mark the times at which the lamp was turned on or off and of Hase injection into the reactor vessel.

274x192mm (300 x 300 DPI)

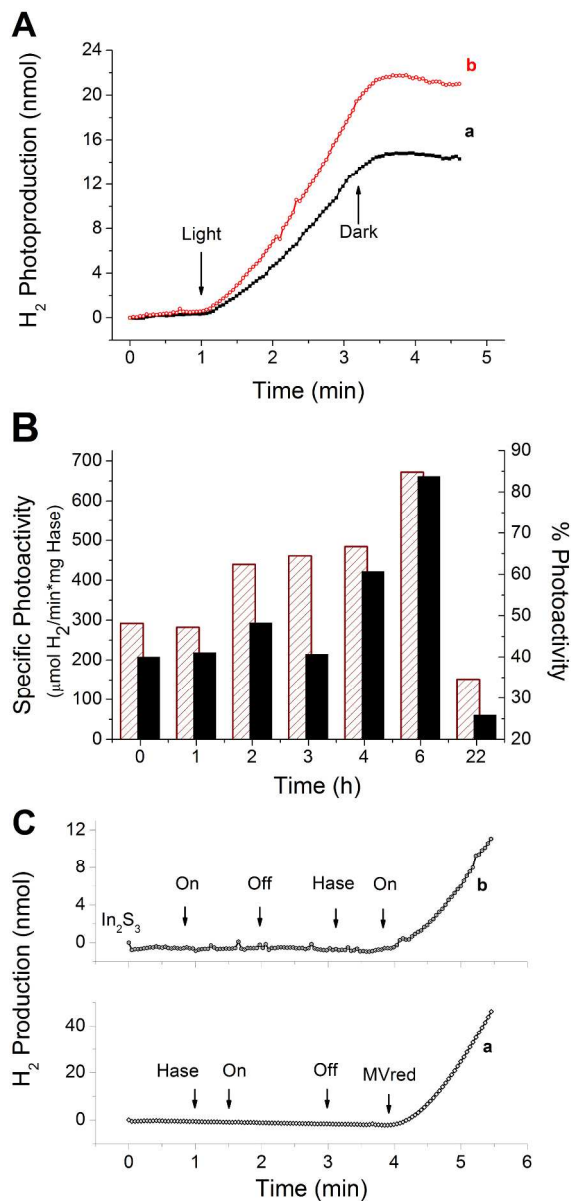

Figure 4. Photocatalytic production of H<sub>2</sub> by Dv. [NiFeSe] Hase in combination with In<sub>2</sub>S<sub>3</sub> particles monitored by mass spectrometry. Measurements were performed at 37°C in 50 mM Tris-HCl 0.2 M sodium sulfite at pH 7. (A) The lines represent H<sub>2</sub> evolution with no previous incubation of the enzyme with the In<sub>2</sub>S<sub>3</sub> (a) or after 3 hours of incubation of Hase with In<sub>2</sub>S<sub>3</sub> at 4°C in a roller mixer (b). (B) Striped column bars represent the specific activity of H<sub>2</sub> photoproduction by Hase after different incubation times. Black column bars represent the % of photoactivity of Hase compared to the specific activity of the sample measured with reduced MV as electron donor. (C) Negative controls of photoactivity monitored by mass spectrometry. The lines represent the H<sub>2</sub> evolution under white light illumination with only Hase (a) and only In<sub>2</sub>S<sub>3</sub> (b). The arrows mark the time when the light is on or off and the moment when 10 μL of 0.166 μM Hase or 2 μL of 1 M sodium dithionite is injected into the vessel to reduce the MV.

160x334mm (300 x 300 DPI)

Figure 5. Percentage of Dv. [NiFeSe] Hase activity retained by In<sub>2</sub>S<sub>3</sub> particles after incubation periods of 1, 3, 4 and 6 hours. The white and striped bar areas represent the % of Hase activity (measured with reduced MV) in the supernatant and In<sub>2</sub>S<sub>3</sub> particles fractions respectively. Black bars represent the % of H<sub>2</sub> photobiocatalytic production in the In<sub>2</sub>S<sub>3</sub> particles fraction compared to the Hase activity with reduced MV. Measurements were done at 37°C in 50 mM Tris-HCl 0.2 M sodium sulfite at pH 7.

45 ABSTRACT. An interesting strategy for photocatalytic production of hydrogen from water and  
46  
47 sunlight is the formation of a hybrid photocatalyst that combines an inorganic semiconductor  
48  
49 able to absorb in the visible light spectral range with an enzymatic catalyst for reducing protons.  
50  
51 In this work we study how to optimize the interfacing of In<sub>2</sub>S<sub>3</sub> particles with the soluble form of  
52  
53 [NiFeSe] hydrogenase from *Desulfovibrio vulgaris* Hildenborough by means of its initial H<sub>2</sub>  
54  
55 photoproduction rate. The kinetics of the photocatalytic process was studied by membrane-inlet  
56  
57  
58  
59  
60

1  
2  
3 mass spectrometry, in order to optimize the interaction between both components of the hybrid  
4 photocatalyst. Membrane-inlet mass spectrometry allows measuring in the same experiment, for  
5  
6 comparison, the rate of H<sub>2</sub> production by the photocatalyst hybrid directly in the aqueous  
7  
8 solution in real time and the result of a standard assay of the hydrogenase activity. An incubation  
9  
10 period of 6 hours under mild stirring of hydrogenase with In<sub>2</sub>S<sub>3</sub> particles was necessary for  
11  
12 optimal interaction of the enzyme molecules with the porous surface of the semiconductor. A  
13  
14 turnover frequency of the NiFeSe Hydrogenase (TOF<sub>Hase</sub>) for H<sub>2</sub>-photobioproduction of 986 s<sup>-1</sup>  
15  
16 was measured under the optimized conditions. This means that the immobilized hydrogenase has  
17  
18 a photocatalytic efficiency for H<sub>2</sub> generation which is 94% of that obtained in the standard  
19  
20 specific activity test of H<sub>2</sub> production using reduced methyl viologen as electron donor.

## 32 **Introduction**

33  
34 Hydrogen is considered a clean energy vector, although nowadays most hydrogen is still  
35  
36 produced from fossil fuels or by water electrolysis using noble metals as electrocatalysts.<sup>1</sup>  
37  
38 Therefore, efficient photocatalytic production of hydrogen from water and sunlight is currently a  
39  
40 major goal of research towards a sustainable energy generation.<sup>2</sup> An interesting strategy for this  
41  
42 purpose is the formation of a hybrid photocatalyst that combines an inorganic semiconductor  
43  
44 able to absorb in the visible light spectral range with a non-noble metal inorganic<sup>3</sup> or enzymatic<sup>4</sup>  
45  
46 catalyst for reducing protons. Many metal sulfide semiconductors have attracted much attention  
47  
48 due to their band gap in the energy range of visible light radiation and their conduction band  
49  
50 energy level situated above that required for reducing protons.<sup>5</sup> Some of them, specially CdS,  
51  
52 have shown excellent properties for photocatalytic production of hydrogen under visible light in  
53  
54  
55  
56  
57  
58  
59  
60

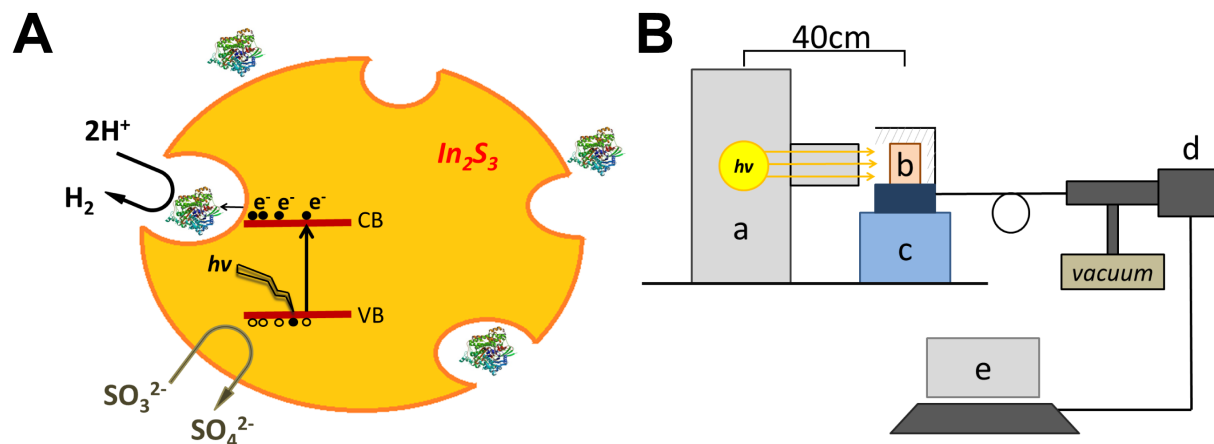

1  
2  
3 aqueous solution using a co-catalyst and a sacrificial compound for holes replenishment.<sup>6</sup>  $\text{In}_2\text{S}_3$  is  
4  
5 another semiconductor frequently used as buffer layer in photovoltaic solar cells<sup>7</sup> or water  
6  
7 splitting photochemical cells<sup>8</sup> because of its interesting electron handling properties. It has also  
8  
9 other potential applications such as visible-light driven photodegradation of organic dyes.<sup>9</sup>  $\text{In}_2\text{S}_3$   
10  
11 is also of interest in photocatalytic production of hydrogen due to its similar band gap energy  
12  
13 ( $E_g \approx 2.2\text{--}2.3\text{eV}$ ) to that of CdS, conduction band potential of  $-0.8\text{V}$  vs RHE and lower toxicity.<sup>5</sup>  
14  
15  $\text{In}_2\text{S}_3$  is easily synthesized by solvothermal reaction with no further modification being needed.<sup>10</sup>  
16  
17

18  
19 In the present work we study a hybrid system based on  $\text{In}_2\text{S}_3$  semiconductor and an enzymatic  
20  
21 co-catalyst for proton reduction in aqueous solution. Hydrogenases are redox metalloproteins  
22  
23 that catalyze efficiently  $\text{H}_2$  production and oxidation under mild conditions.<sup>11</sup> Hydrogenases are  
24  
25 classified according to their metal content of their redox centers. The main groups of  
26  
27 hydrogenases are the [NiFe] and the [FeFe] Hydrogenases, which have a bimetallic complex  
28  
29 coordinated by thiolates, CO and  $\text{CN}^-$  ligands as catalytic site for  $\text{H}_2$  oxidation/production, and  
30  
31 have an electron transfer pathway formed by iron-sulfur clusters that connect the active site with  
32  
33 the enzyme surface.<sup>12</sup> Hydrogenases have shown an excellent electrocatalytic activity with a  
34  
35 turnover frequency (TOF) up to  $10,000\text{ s}^{-1}$  when attached to electrodes.<sup>13</sup> Hydrogenases have also  
36  
37 shown to be good catalysts for photocatalytic hydrogen production when adsorbed on  $\text{TiO}_2$ ,<sup>14</sup>  
38  
39 CdS<sup>15</sup>, CdTe<sup>16</sup> or carbon nitride<sup>17</sup> semiconductors. In particular, [NiFeSe] hydrogenases are well  
40  
41 suited for this purpose because they have a high  $\text{H}_2$  production activity, operational stability and  
42  
43 tolerance to oxygen under reducing conditions.<sup>14,17,18</sup> [NiFeSe] hydrogenases are a subgroup of  
44  
45 the [NiFe] hydrogenases that contain a selenocysteine instead of a cysteine as one of the ligands  
46  
47 to the nickel of its active site, which has a redox potential of around  $-0.400\text{V}$  (vs NHE).<sup>19</sup>

1  
2  
3 A critical step for the rate of photocatalytic hydrogen production is the electron transfer  
4 between the conduction band of the semiconductor and the co-catalyst, in order to minimize  
5 charge recombination in the semiconductor.<sup>3a,20</sup> This issue is especially evident in the case of  
6 using hydrogenases as co-catalysts, in which interfacial electron transfer at the semiconductor  
7 surface is the rate-limiting step of the photocatalytic process.<sup>17,21</sup> Therefore, efforts are needed to  
8 optimize this interaction between the enzyme molecules and the semiconductor particles, so that  
9 the overall rates of photocatalytic H<sub>2</sub> production reach values near to the high turnover rates of  
10 hydrogenases. The Hase-In<sub>2</sub>S<sub>3</sub> electron transfer will be here studied in terms of initial rates of H<sub>2</sub>  
11 production, which is the regime where more reliable data are produced.

22  
23

24 This work will show the very first study on the production of hydrogen with a hybrid  
25 photocatalyst composed by In<sub>2</sub>S<sub>3</sub> particles and the soluble form of [NiFeSe] hydrogenase from  
26 *Desulfovibrio vulgaris* Hildenborough. In<sub>2</sub>S<sub>3</sub> has been chosen because it works under visible light  
27 rather than UV like TiO<sub>2</sub><sup>14</sup>, whereas being Cd-free makes it less toxic than CdS<sup>15</sup> and CdTe<sup>16</sup>. In  
28 order to optimize the interaction between both components of the hybrid photocatalyst we  
29 studied the kinetics of the photocatalytic process by membrane-inlet mass spectrometry. In this  
30 method the reactor for the photocatalytic process has no gas phase and is connected through a  
31 Teflon membrane to the high vacuum line of a mass spectrometer (Scheme 1).<sup>22</sup> This setup  
32 allows to measure the rate of H<sub>2</sub> production directly in the aqueous solution in real time, which  
33 gives us valuable information of the interface process occurring between the hydrogenase and  
34 semiconductor.

## Material and Methods

### Reagents.

All the reagents were used as received without further purification.  $\text{InCl}_3$  99.999%, thiourea 99%, sodium sulfite 98%, TRIS (hydroxymethyl)-aminomethane 99%, HEPES 99.5% and methyl viologen dichloride 98% (MV) were purchased from Sigma-Aldrich. Sodium acetate 99.5% was purchased from Fluka. Sodium hydrogen carbonate 99.999% and hydrochloric acid 37% were purchased from Panreac. Sodium dithionite 87% was purchased from MERK and absolute ethanol was purchased from Scharlau. Low density graphite (LDG, 99.999% purity) rods of 3.05 mm diameter were obtained from Alfa Aesar. Aqueous solutions were prepared using MilliQ deionized water ( $18.2 \text{ M}\Omega \times \text{cm}$ ).  $\text{H}_2$  99.999%, 20%  $\text{H}_2$ : 80% Ar and Ar 99.999% bottles were supplied by Air Liquide.

### Synthesis of $\text{In}_2\text{S}_3$ .

The polycrystalline powder of  $\text{In}_2\text{S}_3$  was synthesized following a known hydrothermal procedure.<sup>10</sup> A Teflon-lined steel high-pressure reactor containing a Pyrex beaker was filled with 50 mL of aqueous solution containing 148 mM  $\text{InCl}_3$  and 178 mM thiourea. 80  $\mu\text{L}$  of HCl 37% were added to acidify the solution and the reactor was set into a stove at 435 K during 48 hours.

1  
2  
3 The reaction product was centrifuged during 15 min at 20°C and 7000 rpm using a BECKMAN  
4  
5  
6 Coulter Avanti J-E centrifuge with a JA 25.5 rotor. The supernatant was discarded and the solid  
7  
8 was redispersed in distilled water. This process was repeated twice. Finally, another  
9  
10 centrifugation-redispersion cycle was carried out using EtOH. The resulting solid was set to dry  
11  
12 for 12 hours at 60°C (Figure S1 of Supporting Information). The reaction yield was 80%.

### 13 14 15 **Characterization techniques.**

16  
17 X-Ray Diffraction (XRD) of the synthesized  $\text{In}_2\text{S}_3$  powder was performed with a Philips  
18  
19 X'Pert Pro PANalytical diffractometer (Cu-K $\alpha$ ,  $\lambda=0.1541874$  nm).  
20  
21

22 Scanning electron microscopy (SEM) was performed with a TM-1000 Tabletop Hitachi  
23  
24 including an X-ray Dispersive Energy detector (EDX).  
25  
26

27 Transmission electron microscopy (TEM) was performed at a point resolution of 0.19 nm with  
28  
29 a 200KV JEOL 2100 transmission electron microscope, equipped with an Oxford Instruments  
30  
31 EDX analyzer. Samples were prepared by taking the powder into an ethanol-filled Eppendorf  
32  
33 and immersed during 15 min into an ultrasound bath. 20  $\mu\text{L}$  of the sample were deposited on a  
34  
35 carbon film-coated 200 mesh copper TEM grid (Electron Microscopy Sciences) and let to dry.  
36  
37

38 The UV-Vis spectrum of the powder was measured using a double beam UV-Vis-NIR Varian  
39  
40 Cary 5000 spectrometer.  
41  
42

43 The surface area of  $\text{In}_2\text{S}_3$  particles was measured using the Brunauer-Emmett-Teller (BET)  
44  
45 method calculation with an Isotherms of Absorption ASAP2020 Micromeritics equipment, after  
46  
47 100 h of  $\text{N}_2$  degassification at room temperature.  
48  
49

50 Voltamperometry and impedance measurements were recorded with an Autolab  
51  
52 Potentiostat/Galvanostat Ecochemie PGSTAT30 with a Frequency Response Analysis (FRA)  
53  
54 module. Impedance measurements were performed at 1000 Hz and 0.482 V vs. NHE. A three-  
55  
56  
57  
58  
59  
60

1  
2  
3 electrode cell configuration was used with an aqueous electrolyte containing 0.1 M sodium  
4 carbonate, 0.1 M sodium acetate and 0.1 M sodium sulfite in the pH range of 4-10. The working  
5  
6 electrode was prepared by depositing 6  $\mu\text{L}$  of a 30 mg  $\text{In}_2\text{S}_3$  suspension in 1 mL of EtOH onto a  
7  
8 clean LDG rod, and dried at 100°C under vacuum during 2 hours. The reference electrode was  
9  
10 Ag/AgCl (3 M NaCl) from BAS and a Pt wire (0.5 mm diameter, Goodfellow) was used as  
11  
12 counter electrode. Cyclic voltammetry for the electrochemical characterization of  $\text{In}_2\text{S}_3$  was  
13  
14 performed using a LDG- $\text{In}_2\text{S}_3$  working electrode in 100 mM phosphate buffer pH 7.5.  
15  
16  
17  
18  
19

#### 20 **D. vulgaris [NiFeSe] hydrogenase purification and catalytic activity assay.**

21  
22 The recombinant soluble form of *D. vulgaris* Hildenborough [NiFeSe] hydrogenase (Hase)  
23  
24 was isolated and purified with a molecular weight of 85 kDa as reported.<sup>23</sup> The  $\text{H}_2$ -production  
25  
26 activity of the enzyme was measured by membrane-inlet mass spectrometry.<sup>24</sup> The output signal  
27  
28 of the mass spectrometer (Pfeiffer Prisma) for each mass value expressed as a current signal is  
29  
30 proportional to the concentration of  $\text{H}_2$  dissolved in the reaction vessel.<sup>24</sup> The output signal of the  
31  
32 spectrometer for mass 2 was calibrated first by saturating the reactor solution with 100%  $\text{H}_2$ . The  
33  
34 catalytic activity of the hydrogenase was measured in a 10 mL solution of 1 mM MV in pH 7.0,  
35  
36 50 mM Tris-HCl buffer. The solution was purged with 100% Ar and then the reactor was closed,  
37  
38 leaving no gas phase inside. A 10  $\mu\text{L}$  solution of 0.166  $\mu\text{M}$  Hase, previously activated under  $\text{H}_2$   
39  
40 atmosphere as said below, was injected to the reactor through a rubber septum with gastight  
41  
42 syringes (SGE Analytical Science). The mass spectrometer was set to monitor mass 2 ( $\text{H}_2$   
43  
44 production) and the reaction was initiated by injecting 2  $\mu\text{L}$  of 1 M sodium dithionite into the  
45  
46 vessel for reducing the methyl viologen. The Hase activation process consisted on adding 1  $\mu\text{L}$   
47  
48 of 10 mM sodium dithionite to 50  $\mu\text{L}$  of anaerobic enzyme solution in a glass vial with a rubber  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 Suba Seal septum (Sigma-Aldrich) and then incubating the solution under 100% H<sub>2</sub> atmosphere  
4  
5 during 10 min at room temperature.  
6  
7

### 8 **Photocatalytic hydrogen production by the *D. vulgaris* [NiFeSe]Hase-In<sub>2</sub>S<sub>3</sub> hybrid.**

9  
10 A typical experiment was started by incubating at 4°C 0.26 pmol of Hase with 22.1 μmol of  
11 In<sub>2</sub>S<sub>3</sub> in 10 mL of 50 mM Tris-HCl, pH 7.0 solution containing 0.2 M sodium sulfite. Sulfite was  
12 selected as electron donor according to published work.<sup>6a</sup> Alternative sacrificial electron donors  
13 such as acetate or sodium sulfide were tested in the preliminary study of the system, finding out  
14 that they were not as effective (data not shown). The suspension was stirred at 60 rpm speed on a  
15 roller mixer (SRT9D). The incubation times monitored were 1, 2, 3, 4, 6 and 22 hours. Each  
16 aliquot of In<sub>2</sub>S<sub>3</sub>-Hase mixture was placed in the reactor vessel connected to the mass  
17 spectrometer, which was closed avoiding the presence of a gas phase for measuring the  
18 photoproduction of H<sub>2</sub>. The Hase was activated by bubbling the solution with 20% H<sub>2</sub>: 80% Ar  
19 gas mixture during 10 minutes. Afterwards 100% Ar was bubbled to remove all the H<sub>2</sub> from the  
20 solution (monitored by the decrease of mass 2 signal). Finally, the reactor was irradiated with  
21 white light coming from a Solar simulator 450W Xenon lamp. The distance from the light source  
22 to the reactor was 40 cm (Scheme 1). A black box covered the experimental setup to avoid any  
23 light reaching the reaction vessel except that produced by the xenon lamp. The power of light  
24 source was measured with a Delta OHM HD 2302.0 LightMeter, yielding 1.5 ± 0.1 W x m<sup>-2</sup>  
25 within the range 315 – 400 nm and 368 ± 1 W x m<sup>-2</sup> within the range 400 – 1050 nm. The rate of  
26 H<sub>2</sub> photoproduction in the reactor solution was measured by monitoring the evolution of mass 2  
27 signal with time at the mass spectrometer. Control experiments were performed in absence either  
28 of semiconductor or hydrogenase under equal setup conditions.

## Semiconductor Characterization

The  $\text{In}_2\text{S}_3$  powder obtained by the hydrothermal synthetic route described above displayed an orange-reddish colour (Fig. S1) and was characterized by different techniques. Transmission and Scanning electron microscopies (TEM-SEM) were used to determine the geometry and size of the powder particles.

**Figure 1.** (A, B) TEM images showing two different particles of  $\text{In}_2\text{S}_3$ . (C, D) SEM images from panoramic and magnified  $\text{In}_2\text{S}_3$  powder aggregates, respectively. (E) (a) XRD Diffractogram obtained from the synthesized  $\text{In}_2\text{S}_3$ . (b) XRD reference pattern of  $\text{In}_2\text{S}_3$  (ref. code 01-084-1385)

The TEM images show two typical  $\text{In}_2\text{S}_3$  particles ranging 50-100 nm in diameter, with near-hexagonal shape (Figure 1A,B). It can also be appreciated that the particles comprise several crystalline domains, separated by typical grain boundaries. Scanning electron microscope revealed spherical particle aggregation with a broad distribution of sizes, which range from 2 to 15 μm of diameter (Figure 1C,D). The XRD diffractogram is displayed in Figure 1E, where (a) is the experimental XRD from the powder and (b) is the reference diffractogram, indicating the Miller indices, of cubic  $\alpha\text{-In}_2\text{S}_3$ . The latter is a spinel structure with disordered cation vacancies,

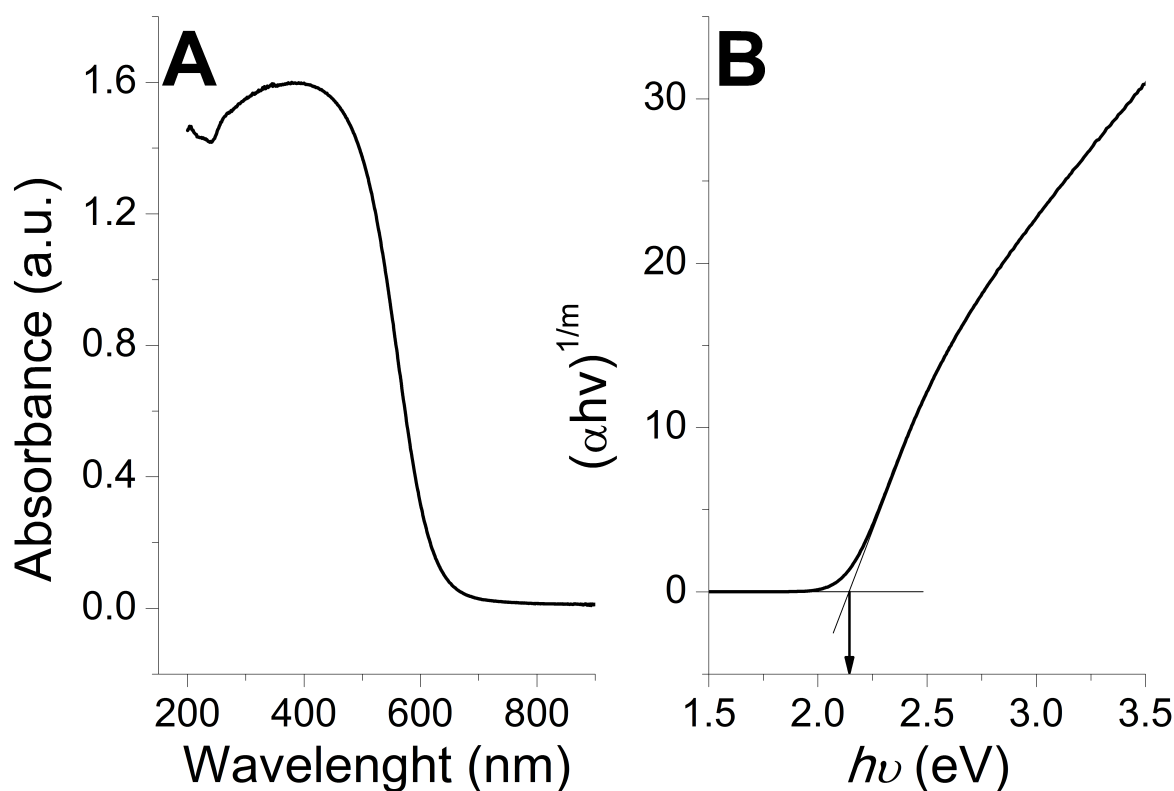

1  
2  
3 usually obtained in this type of preparations instead of the thermodynamically more stable  
4 tetragonal  $\beta$ - $\text{In}_2\text{S}_3$  form, which differs from it only in having the cation vacancies ordered  
5 according to a specific pattern. The additional XRD peaks of the  $\beta$ - $\text{In}_2\text{S}_3$  form, which appear due  
6 to the said ordering and are visible in the corresponding reference diffractogram (ref. code 01-  
7 084-1385), are not visible here. The diffractogram is thus in agreement with the reference  
8 structure and yields a crystal domain size of ca. 37.2 nm using Scherrer's formula.<sup>10,25</sup> Moreover,  
9 the crystal domain size value is in agreement with the TEM observed particle size.

20 The band gap of the synthesized  $\text{In}_2\text{S}_3$  was determined from the diffuse reflectance UV-Vis  
21 spectrum, subjected to the Kubelka-Munk transformation, by means of a Tauc plot (Figure 2).  
22 The measurement yielded a 2.1 eV band gap, as deduced from the linear segment in the region  
23 above the gap when  $(\alpha h\nu)^2$  was plotted against the photon energy (evidencing a direct gap). This  
24 result is in agreement with the value obtained for  $\text{In}_2\text{S}_3$  powder in earlier works<sup>10,25,26</sup> and close to  
25 the 2.0 eV value measured for a well crystallized material.<sup>27</sup> The specific area of the  $\text{In}_2\text{S}_3$  powder  
26 was measured using the Brunauer-Emmett-Teller (BET) method, obtaining a value of  $40.6 \pm 0.3$   
27  $\text{m}^2/\text{g}$  and a total pore volume of  $0.168 \text{ cm}^3/\text{g}$ . The average pore width was 16.5 nm. The pore area  
28 distribution is shown in Figure S2.

37  
38  
39

40 The surface charge on the  $\text{In}_2\text{S}_3$  was studied by deposition of the semiconductor particles on  
41 LDG electrodes and measuring the interfacial capacitance versus the solution pH by impedance  
42 experiments.<sup>28</sup> The  $\text{In}_2\text{S}_3$ -LDG electrode showed a capacitance maximum at pH 7 (Figure S3),  
43 which suggests that surface groups have a pKa value around 7.<sup>28,29</sup> Moreover, the capacitance  
44 values decreased more when the pH was changed to acidic values than when changed to basic  
45 ones. These results suggest that the semiconductor particles are almost without surface charge at  
46 pH 5 or lower, whereas there is a net negative charge at neutral pH.<sup>28</sup> This conclusion was  
47  
48  
49  
50  
51  
52  
53

60

confirmed by the fact that semiconductor particles aggregation was observed at pH 5 and not at pH 7.

Although the CB energy level of  $\text{In}_2\text{S}_3$  has been reported,<sup>5</sup> we accomplished the electrochemical characterization of a LDG- $\text{In}_2\text{S}_3$  modified electrode to evaluate the redox potential of the semiconductor (Figure S4) even knowing that the electrochemical reversibility is not ideal. The value obtained from the standard redox potential is  $\approx -0.2$  vs. RHE under irradiation, indicating that there is a fair overpotential to make possible the electron transfer to Hase.

**Figure 2.** A) UV/Vis absorbance spectrum of  $\text{In}_2\text{S}_3$ . B) Plot of direct band gap of  $\text{In}_2\text{S}_3$ , where  $\alpha$  corresponds to absorption coefficient,  $h$  corresponds to Plank Constant,  $\nu$  to incident photon

### 8 9 **Photoproduction of hydrogen by the hybrid $\text{In}_2\text{S}_3$ /Hase photocatalyst**

10  
11 Sodium sulfite was chosen as sacrificial compound for the photocatalytic experiments because  
12  
13 it has given excellent results with sulfide semiconductors.<sup>6a</sup> Prior to any photoactivity  
14  
15 measurement we have measured the effect of the presence of sulfite on the specific activity of the  
16  
17 enzyme for  $\text{H}_2$  production using reduced methyl viologen at 1 mM concentration as electron  
18  
19 donor. The specific activity of *D. vulgaris* [NiFeSe] Hase measured by mass spectrometry in  
20  
21 Tris-HCl, pH 7, containing 0.2 M sulfite was  $1140 \pm 45 \mu\text{mol H}_2 \times \text{mg}^{-1} \text{Hase} \times \text{min}^{-1}$ . In absence  
22  
23 of sulfite the specific activity of the enzyme was  $3763 \pm 221 \mu\text{mol H}_2 \times \text{mg}^{-1} \times \text{min}^{-1}$ , indicating  
24  
25 that sulfite decreased 3-fold the catalytic turnover of the Hase.  
26  
27  
28  
29

30  
31 The photobiocatalytic production of  $\text{H}_2$  was studied using mixtures of Hase and  $\text{In}_2\text{S}_3$ . Such  
32  
33 mixtures were prepared by incubating the Hase in presence of  $\text{In}_2\text{S}_3$  particles dispersed in an  
34  
35 aqueous buffer containing 50 mM Tris-HCl 0.2 M sodium sulfite at pH 7. Several incubation  
36  
37 periods were tested, after which the catalytic activity of each preparation towards  $\text{H}_2$   
38  
39 photosynthesis was measured. Figure 3 shows the  $\text{H}_2$  production kinetics for the case in which  
40  
41 there was no previous incubation time. The experiment started with the reactor containing only  
42  
43  $\text{In}_2\text{S}_3$  and sulfite, the electron donor. The solution was irradiated from minute 1 to minute 2 with  
44  
45 no production of  $\text{H}_2$  during that time frame. Afterwards the Hase sample was injected inside the  
46  
47 reaction vessel under dark conditions, allowing 1 min to mix with  $\text{In}_2\text{S}_3$  under magnetic stirring.  
48  
49 When the light was switched on again  $\text{H}_2$  production, monitored with the mass spectrometer, was  
50  
51 observed almost immediately. Switching off the light source (min 5) interrupted the  $\text{H}_2$   
52  
53 production inside the reactor, and after a delay period the  $\text{H}_2$  production monitored started to  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 decrease. When the illumination was restored (min 7) the photobiocatalytic H<sub>2</sub> production rate  
4  
5 also was restored. When irradiated the steady state rate of the photocatalytic system was 292  
6  
7  $\mu\text{mol H}_2 \times \text{mg}^{-1} \text{Hase} \times \text{min}^{-1}$ , whereas in the absence of light the H<sub>2</sub> production is null. This  
8  
9 kinetic experiment shows that a significant amount of In<sub>2</sub>S<sub>3</sub>-photoexcited electrons that populate  
10  
11 the In<sub>2</sub>S<sub>3</sub> conductive band (CB) were transferred to the Hase's active site successfully, thus  
12  
13 allowing the reduction of two protons to H<sub>2</sub>.  
14  
15  
16  
17  
18  
19  
20

46  
47 **Figure 3.** Photocatalytic production of H<sub>2</sub> by *Dv.* [NiFeSe] Hase mixed with In<sub>2</sub>S<sub>3</sub> particles  
48  
49 monitored by mass spectrometry. The measurements were performed at 37°C in 50mM Tris-  
50  
51 HCl, 0.2 M sodium sulfite at pH 7. The arrows mark the times at which the lamp was turned on  
52  
53 or off and of Hase injection into the reactor vessel.  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 Similar kinetic experiments were run for each of the incubation times tested from 0 to 22 h.  
4  
5 Figure 4A shows the comparison between an experiment with no previous incubation time (a)  
6  
7 and another experiment where the incubation time was 3 h prior to the experiment's run (b).  
8  
9 Both samples were exposed to the lamp irradiation during the same period of time, from min 1 to  
10  
11 min 3. As it can be observed the longer incubation period yielded a higher H<sub>2</sub> production. The  
12  
13 dependence of the specific activity of the hydrogenase for H<sub>2</sub> photobioproduction on the  
14  
15 incubation time with the semiconductor is shown in Figure 4B (striped bars). In general terms a  
16  
17 longer incubation period yielded a higher photobioproduction of H<sub>2</sub>, which did not apply for the  
18  
19 overnight incubation period that proved too long (Figure 4B). The highest photobioproduction  
20  
21 rate was measured after an incubation time of 6 hours, which was  $672 \mu\text{mol H}_2 \times \text{mg}^{-1} \text{Hase} \times$   
22  
23  $\text{min}^{-1}$ . The H<sub>2</sub> photobioproduction rate for each sample can be compared with the measured H<sub>2</sub>  
24  
25 production rate driven by reduced methyl viologen (MV) instead of light, keeping the rest of  
26  
27 conditions equal. For these measurements the light was turned off, and 1 mM MV and 0.2 mM  
28  
29 sodium dithionite were injected into the reactor. This comparison of catalytic activities allows  
30  
31 determining for each sample the efficiency of the photoexcited electron exchange between the  
32  
33 In<sub>2</sub>S<sub>3</sub> and Hase (Figure 4B, black bars). The initial efficiency of the photocatalytic system with  
34  
35 no previous incubation time is 40%, whereas the 6-hour incubation sample yielded 84% H<sub>2</sub>-  
36  
37 photobioproduction rate efficiency; this means that the irradiated In<sub>2</sub>S<sub>3</sub> supplies enough excited  
38  
39 electrons to the enzyme. Overnight incubation times were not an improvement. The  
40  
41 photobioproduction decreased to  $152 \mu\text{mol H}_2 \times \text{mg}^{-1} \text{Hase}^{-1} \times \text{min}^{-1}$  after 22 hours incubation,  
42  
43 whereas the activity with reduced methyl viologen for this sample was 93% of the initial activity  
44  
45 of the Hase before incubation with the semiconductor. This result corresponds to 26%  
46  
47  
48  
49

51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 photocatalytic efficiency, indicating that an excess of incubation time scarcely deteriorates the  
4  
5 Hase, but it does the  $\text{In}_2\text{S}_3$  and/or its interface with the Hase.  
6  
7

8 The photobioactivity towards  $\text{H}_2$  production was also tested for either  $\text{In}_2\text{S}_3$  or Hase as stand-  
9  
10 alone catalyst, Figure 4C. Both cases demonstrated to be unable to produce  $\text{H}_2$  just when  
11  
12 irradiated. In the control experiment with the Hase (Figure 4C, line a) MV was injected at min 4,  
13  
14 yielding  $\text{H}_2$  production in the absence of light, showing that the Hase was active under these  
15  
16 conditions. Regarding the control with  $\text{In}_2\text{S}_3$ , at min 4 of the experiment Hase was added, which  
17  
18 turned into  $\text{H}_2$  production detection only when the reactor was irradiated. These control  
19  
20 experiments show that the photobioproduction of  $\text{H}_2$  needs both components,  $\text{In}_2\text{S}_3$  and Hase, to  
21  
22 be successful.  
23  
24  
25  
26

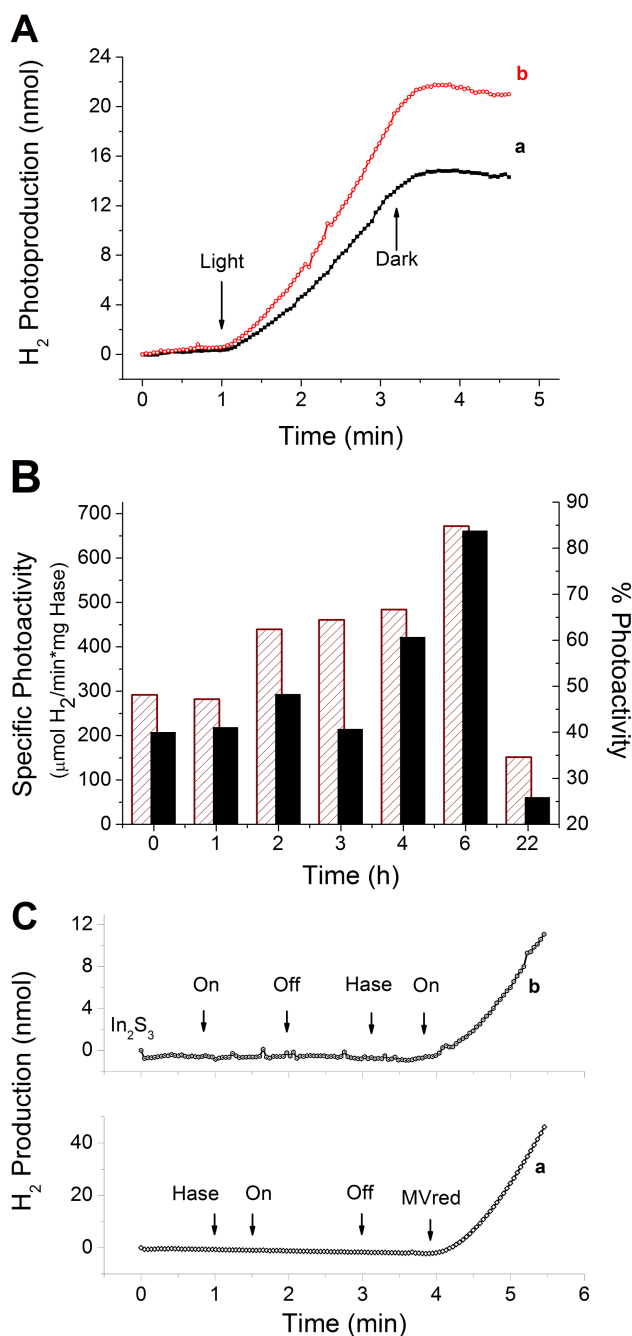

27 A study of the enzyme ratio attached to the  $\text{In}_2\text{S}_3$  particles after incubation and their ability to  
28  
29 photoproduce  $\text{H}_2$  was performed. This study was performed on fresh  $\text{In}_2\text{S}_3$  samples after different  
30  
31 incubation times and consisted on measuring the photoactivity of the Hase/ $\text{In}_2\text{S}_3$  hybrids to  
32  
33 compare them against the activity of Hase remaining in the incubation supernatant. After their  
34  
35 incubation time, the samples were let to sediment under natural gravity during 2 hours. The  
36  
37 supernatant liquid was then separated from the semiconductor powder sedimented at the bottom.  
38  
39 The solid was redispersed with 10 mL of fresh buffer (50 mM Tris-HCl 0.2 M sodium sulfite at  
40  
41 pH 7). The  $\text{H}_2$  production activity of both fractions was measured by mass spectrometry using 1  
42  
43 mM MV as electron donor. Figure 5 represents the percentage of  $\text{H}_2$  production obtained with  
44  
45 the supernatant fraction (bars white area) and the semiconductor particles fraction (bars striped  
46  
47 area). The black bars also represented in Figure 5 show the percentage of photoactivity in the  
48  
49  $\text{In}_2\text{S}_3$  particles fraction compared to the Hase activity measured in the same fraction with reduced  
50  
51 MV. The total  $\text{H}_2$  production activity (sum of the amount obtained with the supernatant and  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 redispersed fractions) measured with reduced MV for samples incubated 1 h, 3 h, 4 h and 6 h  
4  
5 was  $687 \mu\text{mol H}_2 \times \text{mg}^{-1} \text{Hase} \times \text{min}^{-1}$ ,  $1150 \mu\text{mol H}_2 \times \text{mg}^{-1} \text{Hase} \times \text{min}^{-1}$ ,  $798 \mu\text{mol H}_2 \times \text{mg}^{-1}$   
6  
7  $\text{Hase} \times \text{min}^{-1}$  and  $802 \mu\text{mol H}_2 \times \text{mg}^{-1} \text{Hase} \times \text{min}^{-1}$  respectively. These results confirmed that the  
8  
9 enzyme maintained an average of 75.4% of the initial activity after the incubation and the  $\text{H}_2$   
10  
11 photobioproduction assay. The sample incubated during 1h presented 78% of its MV-related  
12  
13 enzymatic activity in the  $\text{In}_2\text{S}_3$ -bound fraction, and 49% of it was photocatalytically active.  
14  
15 Sample 3h showed an increase of the MV-related enzymatic activity in the  $\text{In}_2\text{S}_3$ -bound fraction  
16  
17 up to 92%, whereas only 44% of it was photoactive. Sample 4h retained 85% of the MV-related  
18  
19 enzymatic activity within the  $\text{In}_2\text{S}_3$ -bonded fraction, showing an increase up to 61% of the  
20  
21 photobiochemically produced  $\text{H}_2$ . Sample 6h showed an 89% MV-related enzymatic activity in  
22  
23 the  $\text{In}_2\text{S}_3$ -bonded fraction and the 94% of it was photoactive.  
24  
25  
26  
27  
28

## 29 Discussion

30  
31 The characterization measurements with XRD and TEM of the  $\text{In}_2\text{S}_3$  revealed that the  
32  
33 semiconductor obtained was  $\text{In}_2\text{S}_3$  in its cubic form, with an average crystal domain size of 37  
34  
35 nm and hexagonal nanocrystal shape. The direct band gap value obtained by UV-VIS  
36  
37 spectroscopy at 2.1 eV was the expected for this material,<sup>5</sup> which is thus useful for absorbing  
38  
39 light within most of the visible range. SEM images showed that the aggregate particles were  
40  
41 spheres mostly about 10  $\mu\text{m}$  diameter; flower like and with high level of porosity where the most  
42  
43 common pore size was around 16.5 nm diameter. The diameter of the *Dv* NiFeSe Hase  
44  
45 molecules is around 5 nm,<sup>30</sup> which favors the insertion of the enzyme into the semiconductor  
46  
47 pores during the incubation process. The impedance spectroscopy results indicated that at pH 7  
48  
49 the semiconductor surface had a negative charge, thus preventing massive aggregation of  
50  
51 particles. For this reason, and because the *Dv* NiFeSe Hase has an optimal  $\text{H}_2$ -production activity  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 using reduced MV as electron donor at the pH range 6-7,<sup>23</sup> the incubation of enzyme and  
4  
5 semiconductor particles was done at pH 7. Our results show that the Hase has great affinity for  
6  
7 the semiconductor, as after 1 h incubation most of the active enzyme was attached to the  
8  
9 semiconductor particle fraction and not in the solution one. Therefore, we are indeed forming an  
10  
11 In<sub>2</sub>S<sub>3</sub>/Hase hybrid. Such high affinity for the attachment with a semiconductor has also been  
12  
13 reported for the NiFeSe Hase from *Desulfomicrobium baculatum* with TiO<sub>2</sub> particles.<sup>31</sup>

**Figure 4.** Photocatalytic production of H<sub>2</sub> by *Dv.* [NiFeSe] Hase in combination with In<sub>2</sub>S<sub>3</sub> particles monitored by mass spectrometry. Measurements were performed at 37°C in 50 mM Tris-HCl 0.2 M sodium sulfite at pH 7. (A) The lines represent H<sub>2</sub> evolution with no previous incubation of the enzyme with the In<sub>2</sub>S<sub>3</sub> (a) or after 3 hours of incubation of Hase with In<sub>2</sub>S<sub>3</sub> at 4°C in a roller mixer (b). (B) Striped column bars represent the specific activity of H<sub>2</sub>

1  
2  
3 photoproduction by Hase after different incubation times. Black column bars represent the % of  
4  
5 photoactivity of Hase compared to the specific activity of the sample measured with reduced MV  
6  
7 as electron donor. (C) Negative controls of photoactivity monitored by mass spectrometry. The  
8  
9 lines represent the H<sub>2</sub> evolution under white light illumination with only Hase (a) and only In<sub>2</sub>S<sub>3</sub>  
10  
11 (b). The arrows mark the time when the light is on or off and the moment when 10 μL of  
12  
13 0.166 μM Hase or 2 μL of 1 M sodium dithionite is injected into the vessel to reduce the MV.  
14  
15  
16  
17

18  
19 Irradiation of the mix of Hase and In<sub>2</sub>S<sub>3</sub> with visible light clearly led to immediate production  
20  
21 of H<sub>2</sub> with a high rate as monitorised *in situ* in aqueous solution by membrane-inlet mass  
22  
23 spectrometry. This photocatalytic activity requires both the presence of In<sub>2</sub>S<sub>3</sub> and Hase and, as  
24  
25 discussed above, both components are attached. Note, however, that mere retention of Hase by  
26  
27 In<sub>2</sub>S<sub>3</sub> is not enough: while the proportion of Hase retained after only 1 h of incubation is similar  
28  
29 to that retained after 6 h (see Fig. 5), more prolonged incubation leads to higher photoactivity.  
30  
31 These results suggest that binding the enzyme to the solid to achieve the most active state is a  
32  
33 slower process. In any case, it is clear that In<sub>2</sub>S<sub>3</sub> is able to excite electrons from its valence band  
34  
35 with visible radiation, to use the sulfite in solution as hole scavenger and to transfer the excited  
36  
37 electrons at the CB to the efficiently attached Hase, which catalyzes the reduction of 2 protons to  
38  
39 H<sub>2</sub>. This confirms that the CB has a high enough energy level for thermodynamically favoring  
40  
41 the donation of electrons to the Hase, which has a redox potential of approximately -0.4 V vs  
42  
43 NHE to drive its catalytic activity.<sup>32</sup> Indeed, the flat-band potentials measured for In<sub>2</sub>S<sub>3</sub> films on  
44  
45 fluorine-doped tin oxide are between -0.7 and -0.9 V.<sup>33</sup> Efficient photocatalysis with redox  
46  
47 metalloenzymes not only requires favorable thermodynamics, it also requires fast kinetics of  
48  
49 electron transfer from the semiconductor surface to the exposed redox site of the enzyme (the  
50  
51 distal 4Fe4S cluster in the case of hydrogenases).<sup>4</sup>  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 Our experimental setup is very appropriate for evaluating this step of the photocatalytic process,  
4 as we measure the kinetics of product formation directly in the aqueous solution in real time.  
5  
6 Furthermore, it allows comparing directly in the same measurement the rate of the photocatalytic  
7  
8 process with the hydrogenase specific activity using the standard electron donor for its H<sub>2</sub>-  
9  
10 production assays: reduced MV.<sup>33</sup> In order to be sure that the kinetics of the overall  
11  
12 photocatalytic process were not limited by the photochemical properties of the semiconductor we  
13  
14 have done the measurements with a great excess of In<sub>2</sub>S<sub>3</sub> over the amount of attached Hase.  
15  
16 Thus, we have expressed the H<sub>2</sub>-photobioproduction activity per mg of Hase added rather than  
17  
18 per mg of the photocatalytic In<sub>2</sub>S<sub>3</sub>/Hase hybrid. This allows direct comparison with the specific  
19  
20 activity of the Hase by the standard procedure and optimization of the In<sub>2</sub>S<sub>3</sub>/Hase interface. Our  
21  
22 results show that the best photocatalytic results were obtained after 6 hours of incubation of Hase  
23  
24 with the In<sub>2</sub>S<sub>3</sub> under mild stirring. Under those conditions, 84% of photocatalytic efficiency is  
25  
26 reached when comparing with the total Hase specific activity in solution and on the  
27  
28 semiconductor surface, whereas it increases up to 94% when considering only attached Hase.  
29  
30 Therefore, we have almost obtained an optimal In<sub>2</sub>S<sub>3</sub>/Hase interface in which the photocatalytic  
31  
32 process is not rate-limited by electron transfer between semiconductor and enzyme.

**Figure 5.** Percentage of *Dv.* [NiFeSe] Hase activity retained by In<sub>2</sub>S<sub>3</sub> particles after incubation periods of 1, 3, 4 and 6 hours. The white and striped bar areas represent the % of Hase activity (measured with reduced MV) in the supernatant and In<sub>2</sub>S<sub>3</sub> particles fractions respectively. Black bars represent the % of H<sub>2</sub> photobiocatalytic production in the In<sub>2</sub>S<sub>3</sub> particles fraction compared to the Hase activity with reduced MV. Measurements were done at 37°C in 50 mM Tris-HCl 0.2 M sodium sulfite at pH 7.

Fast interfacial kinetics of electron exchange of NiFe Hases (including the one used in this work) with electrodes has been obtained by oriented immobilization of the enzyme modulated by electrostatic interactions between charged groups on the electrode surface and the net dipolar moment of the enzyme surface. In this way the distal 4Fe4S cluster of the Hase is facing the electrode surface.<sup>34</sup> A similar strategy was applied by Brown et al. for oriented attachment of an

1  
2  
3 FeFe hydrogenase to CdS nanorods, in which very fast Hase turnovers of 380-900 s<sup>-1</sup> were  
4 measured for H<sub>2</sub>-photobioproduction.<sup>15</sup> However, in our case the net negative charge of the In<sub>2</sub>S<sub>3</sub>  
5 surface should not favor adequate orientation of the immobilized NiFeSe Hase for fast electron  
6 transfer because the distal 4Fe4S cluster is surrounded by negative charges at neutral pH.  
7  
8 Nevertheless, fast interfacial kinetics of electron transfer has also been obtained by adsorption of  
9 Hases on rough graphite electrode surfaces with pore diameters slightly larger than the size of  
10 the enzyme molecule.<sup>35</sup> In that case, there is a high chance that an enzyme molecule immobilized  
11 inside a pore will have its distal 4Fe4S cluster at a distance of the electrode surface adequate for  
12 fast direct electron transfer, independently of its orientation.<sup>35</sup> In our case, the highly porous  
13 surface of In<sub>2</sub>S<sub>3</sub> may favor the inclusion of the enzyme into the cavities of the solid, allowing an  
14 efficient contact. The pore analysis of the In<sub>2</sub>S<sub>3</sub> indicates an average diameter of 16.5 nm, which  
15 is big enough to host the enzyme. Enzymes hosted in such porous cavities are surrounded by the  
16 semiconductor surface, increasing the probability that an electron excited in the In<sub>2</sub>S<sub>3</sub> migrates to  
17 the distal cluster instead of recombining with a hole. The increase in the photobioproduction  
18 upon longer incubation times up to 6 h is coherent with slow connection kinetics as explained  
19 above. After 1h incubation time almost 80% of the active Hase was bound to the In<sub>2</sub>S<sub>3</sub>, whereas  
20 20% shows activity in the supernatant fraction; however its photobioproduction rate just reached  
21 the 49% of the overall activity. This result indicates a poorly efficient electron transfer from the  
22 CB to the Hase active site; the Hase is interacting with the In<sub>2</sub>S<sub>3</sub> but the In<sub>2</sub>S<sub>3</sub>/Hase electron  
23 transfer is still rate-limiting. After a 6 h incubation period at 4°C in a roller mixer, the Hase  
24 bound to the In<sub>2</sub>S<sub>3</sub> reached 89% of the overall activity, which is a small improvement from 1h,  
25 but the H<sub>2</sub> photobioproduction rate increased up to 94% efficiency of the bound Hase. The  
26 increase in the photobiocatalytic efficiency may be explained by the slow insertion of the Hase  
27

3 molecules into suitable pores, favoring the contact between the Hase and the surrounding  
4  
5 semiconductor and decreasing the importance of Hase orientation for fast electron transfer upon  
6  
7 irradiation of the  $\text{In}_2\text{S}_3$ -Hase catalytic tandem. In this way, the highest turnover frequency of the  
8  
9 NiFeSe Hase ( $\text{TOF}_{\text{Hase}}$ ) we have measured in our system for  $\text{H}_2$ -photobioproduction was  $986 \text{ s}^{-1}$ ,  
10  
11 a value that equals the highest one measured by Brown et al. using CdS nanorods and a FeFe  
12  
13 Hase as photocatalyst hybrid.<sup>15</sup>  
14  
15

## 16 17 18 **Conclusions**

19  
20 The present work shows for the first time the  $\text{H}_2$  production from water photobiocatalyzed by  
21  
22 an  $\text{In}_2\text{S}_3$ -Hydrogenase hybrid catalyst, and powered by visible light.  $\text{In}_2\text{S}_3$  has been demonstrated  
23  
24 as a suitable host for the hydrogenase, managing to transfer the excited electrons into the active  
25  
26 site of the enzyme. The optimum experimental conditions comprise an incubation period of 6  
27  
28 hours; this leads to 89% of the hydrogenase being optimally attached to the semiconductor. The  
29  
30 photobioproduction of  $\text{H}_2$  by this optimal sample was 94% of the total activity measured for the  
31  
32 hydrogenase by classical means, proving the importance of an appropriate interfacing between  
33  
34 the semiconductor particles and the enzymatic co-catalyst to favor the electron transfer from the  
35  
36  $\text{In}_2\text{S}_3$  conduction band to the active site of the *D. vulgaris* [NiFeSe] hydrogenase. The result of  
37  
38 the present work is of particular interest since it opens the possibility that the whole visible light  
39  
40 range, even including a small part of the IR range, may be used for  $\text{H}_2$  photo-generation if V-  
41  
42 substituted  $\text{In}_2\text{S}_3$ , which has evidenced capability for coupling two low energy excitations like in  
43  
44 the Z-scheme of natural photosynthesis,<sup>26</sup> is used as light absorber. Future work founded on the  
45  
46 present results will include the study of long-term  $\text{H}_2$  photobioproduction and accumulation in  
47  
48 gas phase.
